MeasureMind 3D software

1-chip measurement

- in non-changing conditions: σ of one point measurement $< 1\mu\text{m}$
- data reproducibility with different measurements:
 $\sigma < 5\mu\text{m}$

difference

Differences2D (lambda=0.0)

Ladder

- 4 chips on the support structure
- smaller (AA $17,3 \mu\text{m} \times 17.4 \mu\text{m}$)

1st sensor is broken

measurement set-up

- how to set-up coordinate system:

1 global CS

more local CSs

- second way is more convenient for our purpose

measurement set-up

- crucial step is to define measurement datums
- there are no nice features on these chips -> active area corners used as datums
- significant source of systematic errors

final chip features

- two corners on the ROE side

- 3rd feature?

Ladder measurement

3 sensors in GCS (fit):

Ladder measurement

Global CS vs. Local CS:

difference
1st chip

difference
3rd chip

Differences2D (lambda=0.0)

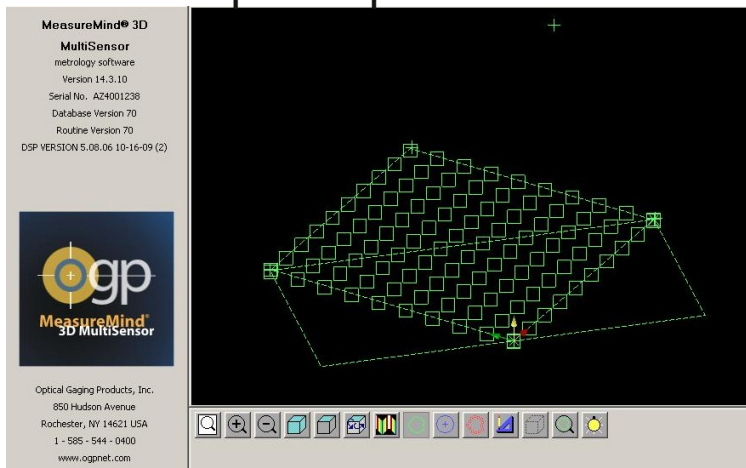

Differences2D (lambda=0.0)

routines in MeasureMind 3D

- user-made steps are saved and then automatically repeated
- saved as a binary file – no hand-editing possible
- some steps may be copied (x,y,z offset)
- “part repeat” option can be used (=>local CS needed)
- however “edge measurement” cannot be copied/repeated since it preserves z value from the original measurement

“part repeat” routine

no repeat (imagine the 10-chips ladder...)

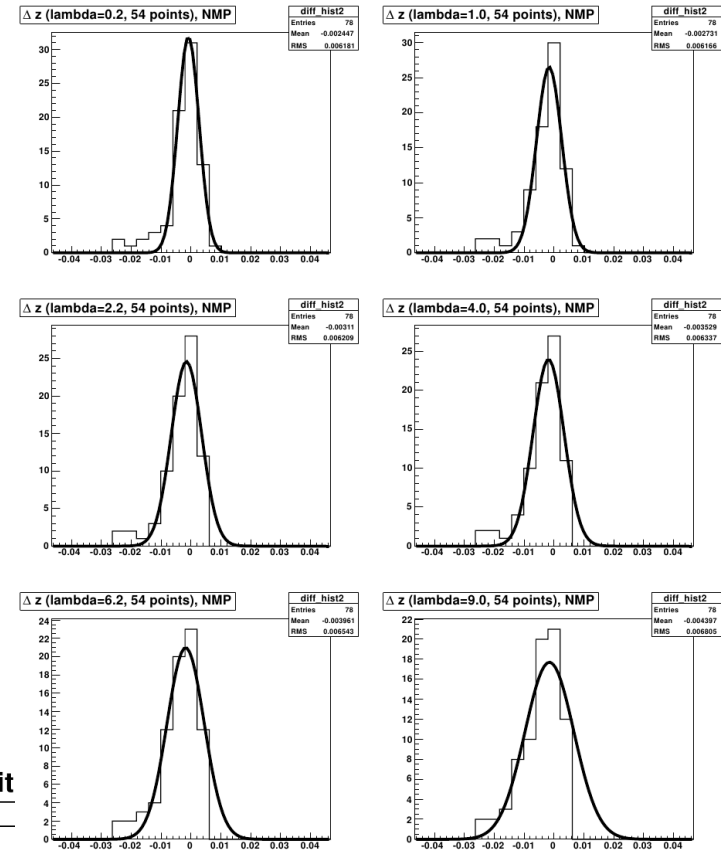

Conclusion

- Ladder measurement can be done fast, once the routine is created
- Precise measurement of part datums is crucial
- MeasureMind routines cannot be easily edited
(=> measuring conditions as stable as possible)

BACKUP

lambda parameter

- controls how much the fit can deviate from the measured values used for the fit
- setting $\lambda > 0$ does not improve the results

Δz in points used for the fit

Δz in points not used for the fit
