

Single electrons UPC pileup

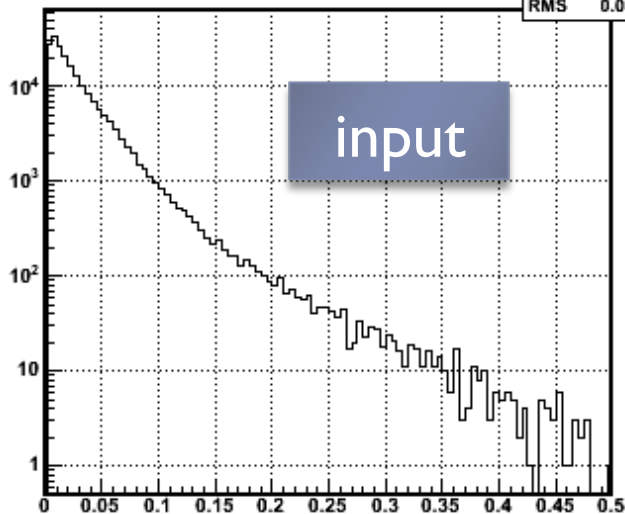

- ▶ Evaluation of the UPC electron contribution to the pileup.
- ▶ Input is the Pt of electrons in $0 < Pt < 0.5$ from Y. Gorbunov.
- ▶ dump the number of bin content (= number of electrons) per bin in a .dat file.
- ▶ Use the .dat file as input for starsim (upgr l 5 geometry) where 1 electron / event is thrown (flat in $|y| < 1$, $\sigma_{v_z} = 20\text{cm}$)

comments

- ▶ Contribution at very low Pt ($<.1$) of extra hits due to UPC electrons is not negligible
- ▶ For higher Pt, we found back a ratio ~ 1 , meaning 1 track leaves 1 hit in each layer.
- ▶ To do : simulations with rapidity $|y|<5$ because even for vertex $\sim 30\text{cm}$, UPC electrons can hit the PXL detector.

Zoomed in $0 < P_t < 0.1$
